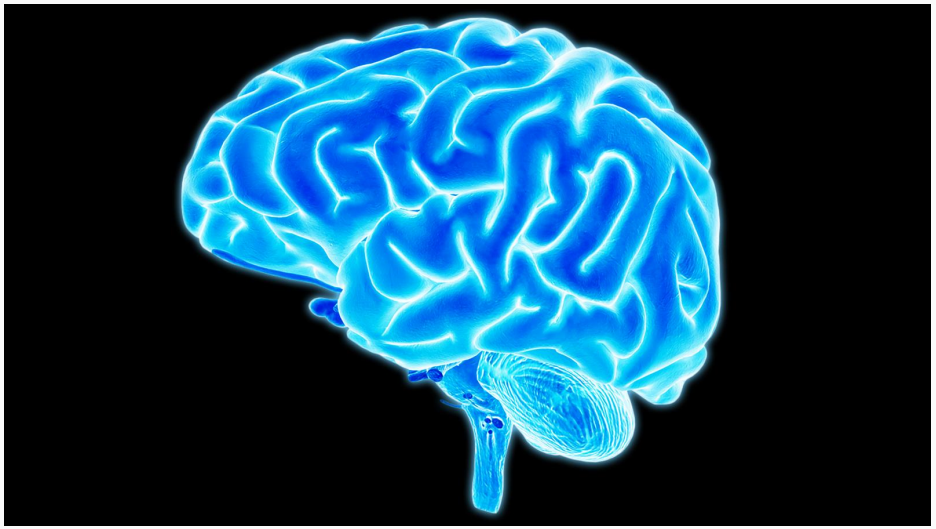
fMRI: Sensing Brain Signal



Goal: **detect semantic meaning in fMRI signal.**

100 billion neurons in the brain

fMRI measures hemodynamic response at ~10^5 different 3mm x 3mm x 3mm voxels

Each voxel represents an average of the activity of the ~10^6 neurons it contains

Prior Work on Connecting a Semantic Space to fMRI Data

[Mitchell et al ‘08] predicts fMRI responses induced by **pictures of concrete nouns**.

[Naselaris et al ‘09] predicts fMRI responses induced by **images of scenes.**

[Pereira et al ‘11] uses the same dataset as Mitchell ‘08, but focuses on **generating words** related to the concrete nouns.

[Naselaris et al ‘11] tries to **reconstruct movie images** from fMRI signals measured while subjects watched movies.

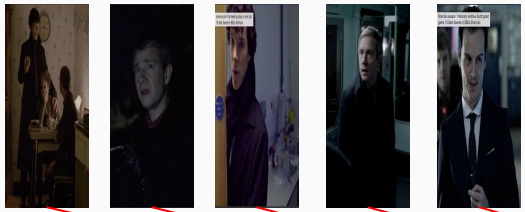
[Wehbe et al ‘14] has subjects **read a chapter of Harry Potter** and predicts fMRI responses for held-out time points.

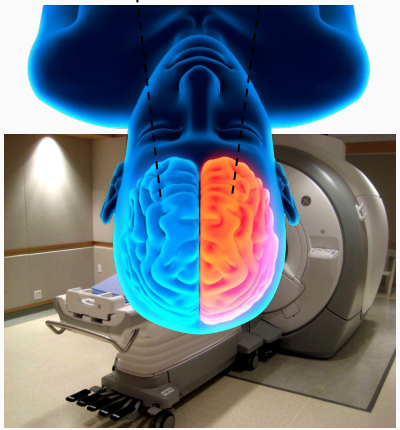
[Huth et al ‘16] reconstructs fMRI responses to **auditory stories**.

[Pereira et al ‘16] decodes fMRI responses to **word clouds and short sentences.**

Main Goal: Decode fMRI Response Semantics

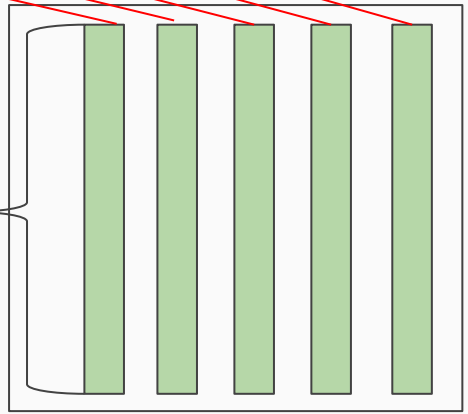
Movie scenes





fMRI Machine

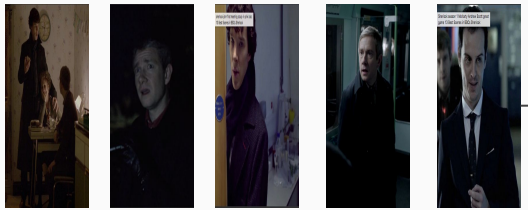
10^5 voxels



fMRI responses

Matching fMRI responses to annotations (Views: fMRI signal, text annotations)

Movie scenes



Annotations of movie scenes

Sherlock and John talk about the murder in an old room with Mrs. Hudson.

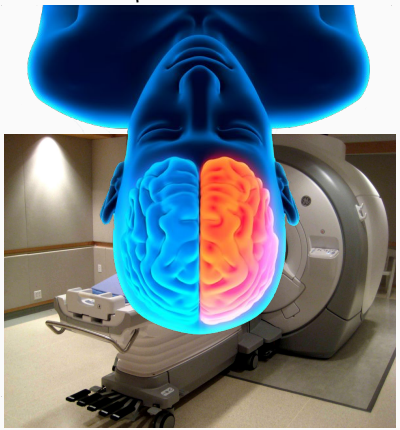
John is worried as Sherlock runs off.

Sherlock enters the door to the chemistry lab, saying "John, I was here the whole time."

Once they get on the subway, John exclaims, "No you weren't!"

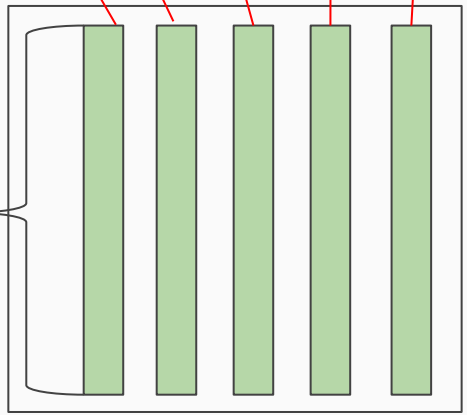
Moriarty arrives and says, "Hello Sherlock, John."

Each movie scene paired with text description from external party.



fMRI Machine

10^5 voxels



fMRI responses

Representing Annotations: Word Embeddings

- To map between fMRI vectors and words, we would like to represent words in vector space
- Goals of embeddings: Preserve some notions of similarity and distance that apply to the words
- Idea: Assign to every word a 100-dim vector
- How?

Training Word Embeddings

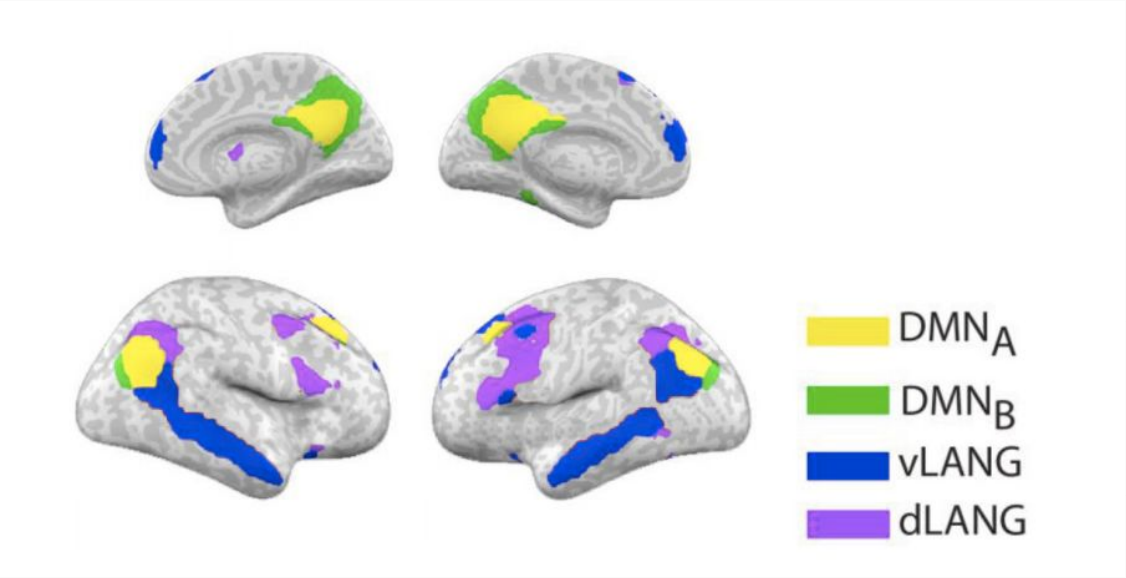
- Idea: Train a predictive model on some task which “captures the meaning of natural language”.
  - Can be an unsupervised task, i.e. “language modeling”.
- Parameters of the model include a subset which are assigned uniquely to each word
  - Initialized randomly
- Training the model on external training set → word vectors
- How to combine word vectors to get “annotation vectors”?

Interesting and Useful Discoveries

- The Shared Response Model (SRM, Chen et al. 2015) helps for decoding text!

- Weighted average word vectors → better semantic context vectors (ICLR 2017 paper, Arora et al)

Brain Regions (ROIs) Studied



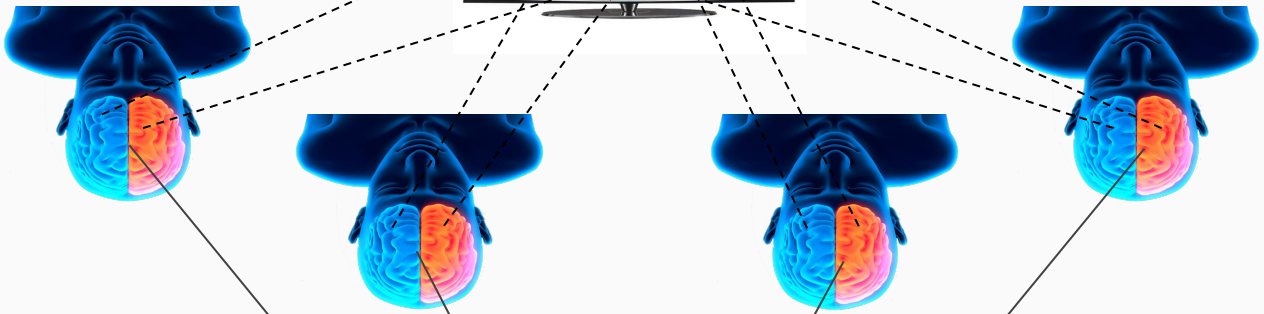
- Default Mode Network (DMN) standard area in literature
  - known to relate to narrative processing
  - DMN-A, -B (2000 voxels)
- Ventral/Dorsal Language (2000 voxels)
- Whole Brain (26000 voxels)
  - voxels with high inter-subject correlation
- Occipital Lobe (6000 voxels)

Leveraging Multiple Subject Views to Extract Better Semantics

Shared Movie Stimulus

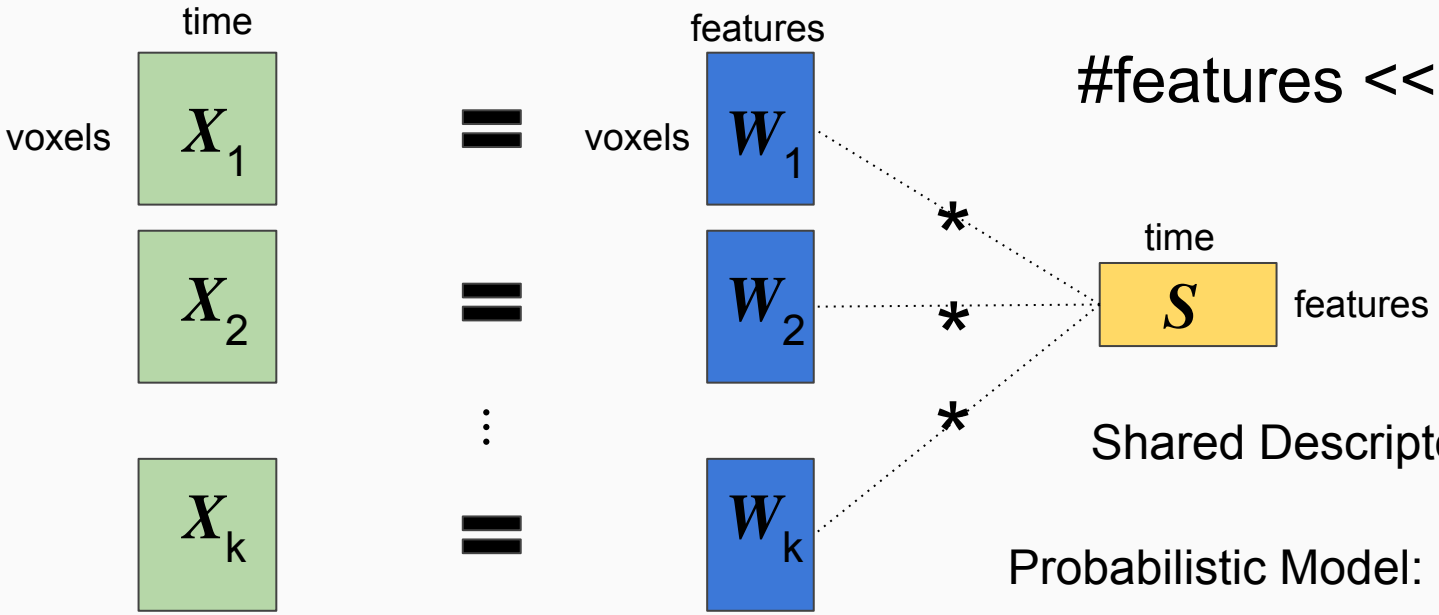
Multiple Subject Responses

Shared fMRI Response



Does aggregating data from multiple individuals help pick up a stronger fMRI signal?

Shared Response Model (SRM, [Chen, Chen, Yeshurun, Hasson, Haxby, Ramadge '15])



#features << #voxels

Shared Descriptor of Semantic Signal

Probabilistic Model:

$$\underset{W^T W=I;S}{\operatorname{argmin}} \sum_{i=1}^{k} \|X_i - W_i S\|_F$$

$$s_t \sim \mathcal{N}(0, \Sigma_s)$$

$$x_{it}|s_t \sim \mathcal{N}(W_i s_t + \mu_i, \rho_i^2 I)$$

Embedding Annotations with Weighted Sums of Word Vectors

Fig. 3. Visualization of Semantic Annotation Vector Weightings: We display an example sentence from the Sherlock annotations, where we have colored important words red, and unimportant words blue. Brighter red means more important, and darker blue means less important.

Using Information (Temporal Dynamics) from the Past

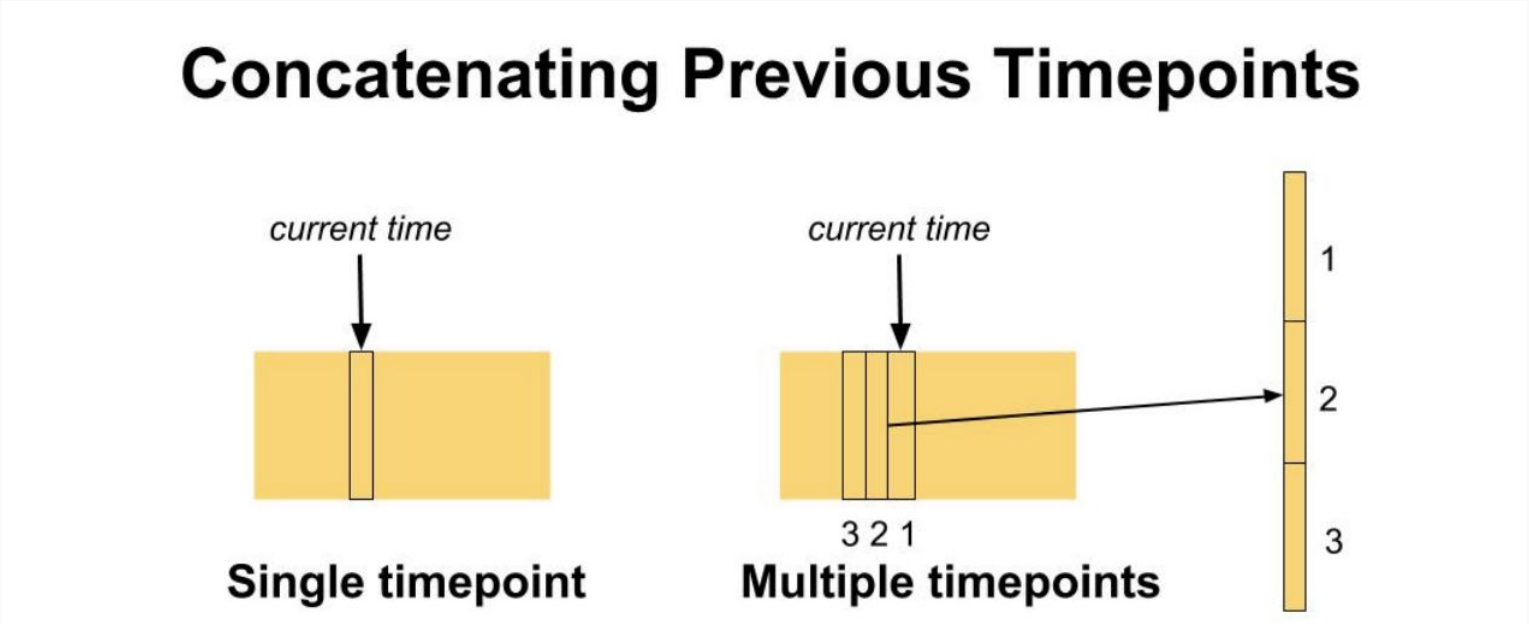


Fig. 4. Visualizing Concatenation: We visualize what the single timestep case looks like compared to a case where we use the previous two timesteps in our featurization as well. The latter case results in a more complicated model, since one of the dimensions of our linear map triples in size.

Linear Maps Between fMRI and Text

Basic Model:

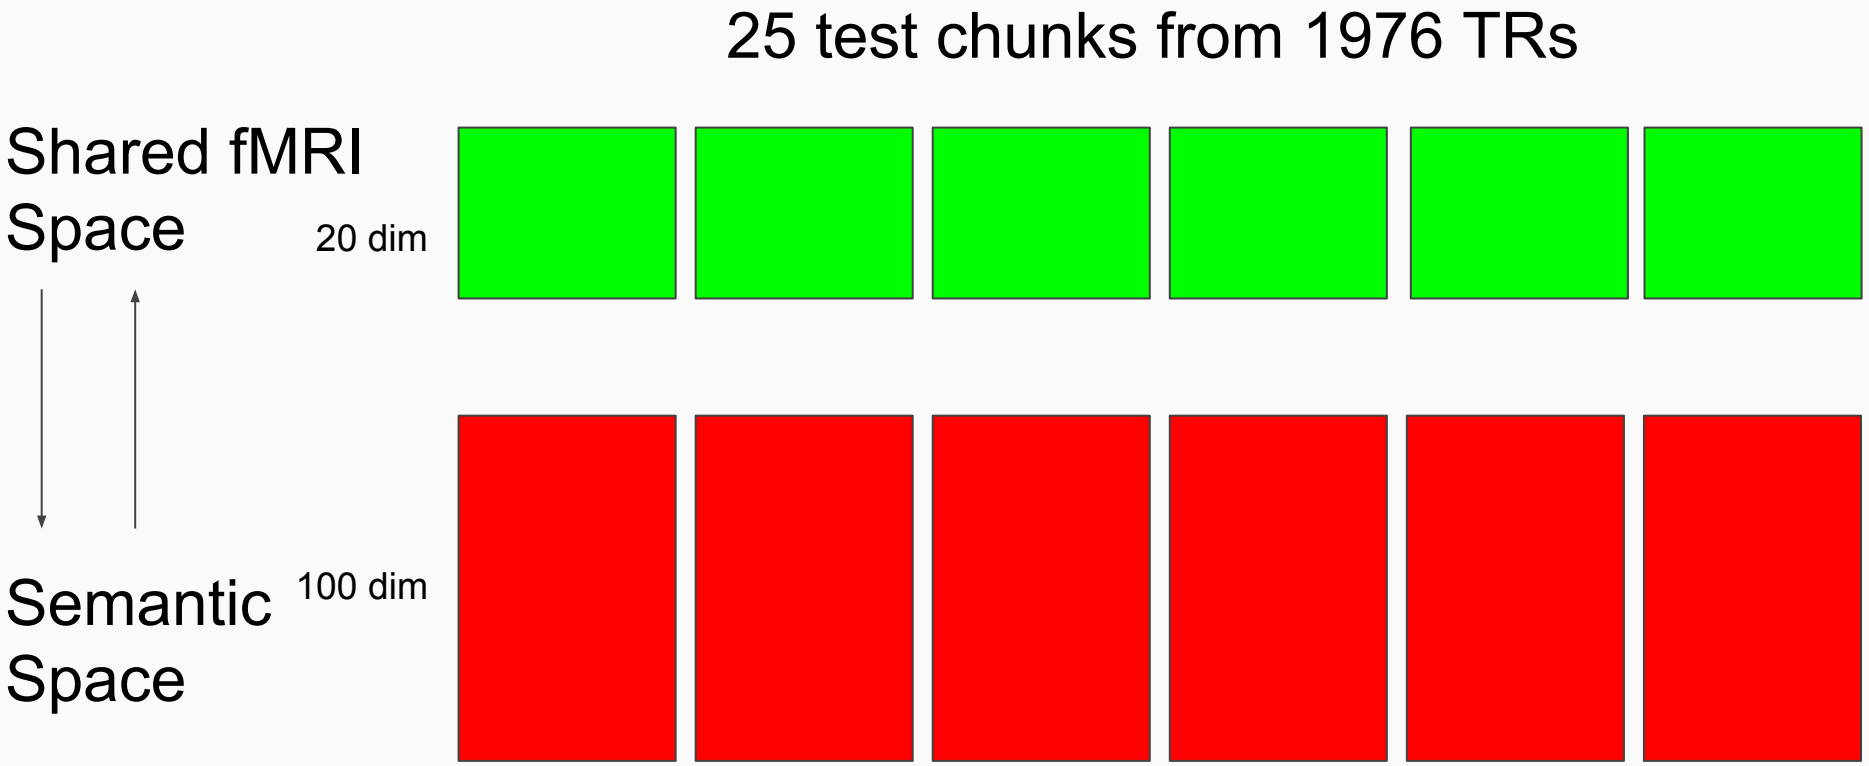
$$WX = Y \quad , \quad W \in \mathbb{R}^{m \times n}$$

X represents the fMRI data matrix (n x T)
Y represents the semantic annotation data matrix (m x T)

Learning the Map:

- Procrustes ($W^TW = I$)
  - Restrict map to “rotations” of the data.
  - Imposes strong constraint on map
- Ridge Regression (penalize l_2 norm $||w||_2$)
  - Classic linear regularization method
  - Restricts map weights to be uniformly small (not sparse)

Evaluation: Scene Classification/Ranking Experiments



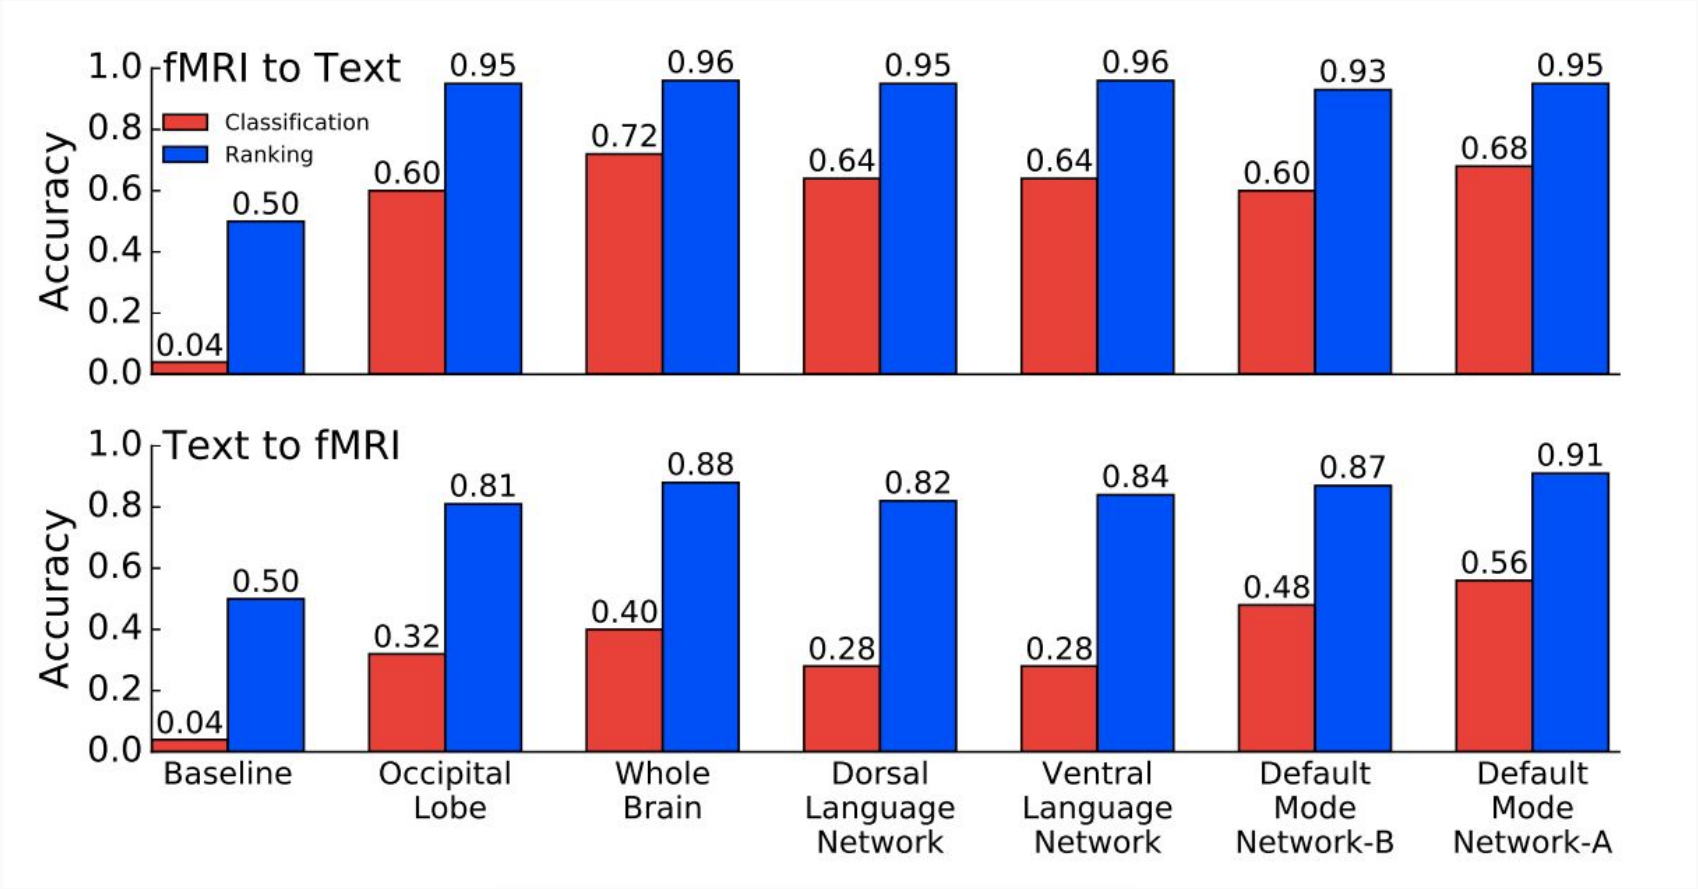
Results: Multiplicative Improvements with our Methods

Mapping Between fMRI Responses and Semantic Representations

fMRI → Text	Maximum	Average
Previous Timesteps vs. None	5.3×	1.8×
Procrustes vs. Ridge	2.8×	1.3×
SRM/SRM-ICA vs. PCA	1.8×	1.3×
Weighted-SIF vs. Unweighted	1.6×	1.2×
Text → fMRI	**Maximum**	**Average**
Previous Timesteps vs. None	2.5×	0.5×
Procrustes vs. Ridge	3.0×	0.8×
SRM/SRM-ICA vs. PCA	2.3×	1.2×
Weighted-SIF vs. Unweighted	1.8×	1.1×

Table 1. Table of Improvement Ratios for Various Algorithmic Parameters: In this table we give the maximum and average improvement ratios for a specific algorithmic technique over another, including usage of previous time steps, SRM/SRM-ICA versus PCA, SIF-weighted annotation embeddings versus unweighted annotation embeddings, and Procrustes versus ridge regression for both fMRI → Text and Text → fMRI. When we use previous timesteps, we consider the results for using $5 - 8$ previous time steps. These numbers are all for the scene classification task. Note that the values from the maximum columns can be seen visually in Figures 6 and 7 respectively.

Results: Top-4% Classification and Average Rank



Results: Comparisons for fMRI → Text (4% Chance)
